Anti-SARS-CoV-2 ELISA (IgA)

- Sensitive ELISA for the determination of IgA antibodies against SARS-CoV-2 with optimised specificity due to the use of sample buffer PLUS
- Use of the spike protein domain S1 as the antigen
- For monitoring the immune response after positive direct pathogen detection
- Fully automated processing and evaluation possible

Technical data

**Antigen**
Domain S1 of the SARS-CoV-2 spike protein expressed recombinantly in human cells, isolate Wuhan-Hu-1

**Calibration**
Semiquantitative; calculation of a ratio from the extinction of the sample and that of the calibrator

**Result interpretation**
EUROIMMUN recommends interpreting results as follows:
- Ratio < 0.8: negative
- Ratio ≥ 0.8 to < 1.1: borderline
- Ratio ≥ 1.1: positive

**Sample dilution**
Serum or plasma, 1:101 in sample buffer PLUS

**Reagents**
Ready for use, with the exception of the wash buffer (10x); colour-coded solutions, in most cases exchangeable with those in other EUROIMMUN ELISA kits. The sample buffer PLUS is not exchangeable and must only be used in combination with the Anti-SARS-CoV-2 ELISA (IgA).

**Test procedure**
60 min (37 °C) / 30 min (37 °C) / 30 min (RT) (sample/conjugate/substrate incubations), fully automatable

**Measurement**
450 nm, reference wavelength between 620 nm and 650 nm

**Test kit format**
96 break-off wells; kit includes all necessary reagents

**Stability**
12 months

**Order number**
EI 2606-9601 A; EI 2606-9620 A (designed especially for processing on the EUROLabWorkstation ELISA)

Clinical significance

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2, previously called 2019-nCoV) belongs to the family of coronaviruses and, like SARS-CoV, is classified in the genus *Betacoronavirus*. At the end of 2019, SARS-CoV-2 was identified as the causative pathogen in a cluster of pneumonia cases of unclear origin. The virus caused an infection wave that has spread rapidly over the world and was declared a pandemic by the WHO at the beginning of 2020.

SARS-CoV-2 is mainly transmitted via aerosols during coughing or sneezing or at close contact with an infected person. Health care personnel and family members are especially at risk. The zoonotic reservoir of the virus appears to be bats. The incubation time of SARS-CoV-2 is three to seven, maximally 14 days. The symptoms of SARS-CoV-2 infection are fever, coughing, breathing difficulties and fatigue. In most patients the infection manifests with symptoms of a mild febrile illness with irregular lung infiltrates. Some patients, especially elderly or chronically ill patients, develop acute respiratory distress syndrome (ARDS). The fatality rate is between 0.6 and 7.2%, depending on the country. In February 2020, the disease caused by SARS-CoV-2 was named COVID-19 by the WHO.

Suitable methods for the diagnosis of SARS-CoV-2 infections are the detection of viral RNA by reverse transcriptase polymerase chain reaction (RT-PCR) or of virus protein by means of ELISA primarily in sample material from the upper (nasopharyngeal or oropharyngeal swab) or lower respiratory tract (bronchoalveolar lavage fluid, tracheal secretion, sputum, etc.). The determination of antibodies enables confirmation of SARS-CoV-2 infection in patients with typical symptoms and in suspected cases. It also contributes to monitoring and outbreak control. For significant serological results, two patient samples should be investigated, one from the acute phase (week 1 of the illness) and one from the convalescent phase (3 to 4 weeks later). Cross reactions with antibodies within the genus *Betacoronavirus* have been described. Currently, there is no medication or vaccine available against infection with this new virus.
The sensitivity was determined by investigating 137 samples from 124 European patients using the Anti-SARS-CoV-2 ELISA (IgG). In these patients, infections with SARS-CoV-2 had been detected by RT-PCR based on a sample taken at the early phase of infection. The serological examination was based on samples collected during the further course of the infection. In samples taken until and including day 10 (time point after symptom onset or positive direct detection), the Anti-SARS-CoV-2 ELISA (IgG) showed a sensitivity of 88.2%. The sensitivity in samples taken between day 11 and 60 was 98.9% for the Anti-SARS-CoV-2 ELISA (IgA) and 84.6% in samples taken after day 60.

The graph shows two individual immune responses in COVID-19 patients measured with the EUROIMMUN Anti-SARS-CoV-2 ELISAs (IgA, IgG) based on the recombinantly expressed spike protein domain S1 and the EUROIMMUN Anti-SARS-CoV-2 NCP ELISA (IgG) using the modified nucleocapsid protein (NCP) as the antigen. Patient 1 (47 years old): The anti-SARS-CoV-2 NCP IgG antibody level was elevated as early as day 8 after the onset of symptoms. Anti-SARS-CoV-2 S1 antibodies (IgA and IgG) were not yet detectable. The follow-up sample taken on day 11 after symptom onset showed an increase in the antibody levels for both Ig classes. Patient 2 (58 years old): The Anti-SARS-CoV-2 S1 IgA antibody level was already highly elevated 12 days after the first positive RT-PCR. In contrast, the levels of anti-SARS-CoV-2 S1 and anti-SARS-CoV-2 NCP IgG antibodies increased only slowly until day 43 after positive RT-PCR.

The time course of antibody secretion and the antibody activity at specific time points can vary significantly. In most patients, antibodies are detectable after day 10 after symptom onset or positive direct detection. In individual cases, however, a significantly delayed synthesis of IgG (> 4 weeks after symptom onset or positive detection) has been reported.

### Specificity

The specificity of the Anti-SARS-CoV-2 ELISA (IgA) was determined by investigating 210 patient sera that were positive, for instance, for antibodies against other human pathogenic coronaviruses, other pathogens or for rheumatoid factors. Additionally, 1052 samples from blood donors, children and pregnant women obtained before the occurrence of SARS-CoV-2 (before January 2020) were analysed. Cross reactions with other human pathogenic coronaviruses were not observed. The specificity of the Anti-SARS-CoV-2 ELISA (IgA) thus amounted to 98.3%.
